Question 1

a)

$$x_s(t) = x(t)s(t) = \sum_{n=-\infty}^{\infty} x(t)\delta(t - nT_s) = \sum_{n=-\infty}^{\infty} x(nT_s)\delta(t - nT_s)$$

where T_s is called the sampling period.

By the modulation property of CTFT: $X_s(j\omega) = \frac{1}{2\pi}X(j\omega) * S(j\omega)$

$s(t)$ is a periodic signal, therefore we should first find its CTFS representation:

$$s(t) = \sum_{k=-\infty}^{\infty} a_k e^{jk\omega_s t}, \omega_s = \frac{2\pi}{T_s}$$

$$a_k = \frac{1}{T_s} \int_{-T_s/2}^{T_s/2} \underbrace{s(t)}_{\delta(t)} e^{-jk\omega_s t} dt \Rightarrow a_k = \frac{1}{T_s}$$

$$s(t) = \sum_{k=-\infty}^{\infty} \frac{1}{T_s} e^{jk\omega_s t} \longrightarrow S(j\omega) = \sum_{k=-\infty}^{\infty} \frac{2\pi}{T_s} \delta(\omega - k\omega_s)$$

$$X_s(j\omega) = \frac{1}{2\pi}X(j\omega) * \sum_{k=-\infty}^{\infty} \frac{2\pi}{T_s} \delta(\omega - k\omega_s) = \sum_{k=-\infty}^{\infty} \frac{1}{T_s} X(j(\omega - k\omega_s))$$

From the Nyquist sampling theorem, the inequality $\omega_s \geq 2\Delta\omega$ should be satisfied so that the shifted replicas of $X(j\omega)$ do not overlap. Thus, it yields perfect reconstruction of the signal $x(t)$ from $x_s(t)$ with no aliasing. So, the minimum sampling rate, $\omega_s = 2\Delta\omega$. The Fourier transform of the sampling system output, $X_s(j\omega)$ can be seen below.

b)

$X(j\omega)$ is not symmetric with respect to y-axis, thus from the symmetry property of CTFT it can be concluded that $x(t)$ is a complex-valued signal.

i)

Since the sampling rate of the signal is equal to the Nyquist rate, the aliasing does not occur. The Fourier transform of $X_s(j\omega)$ is plotted below for $T_s = \frac{\pi}{\Delta\omega}$.

ii)

As it can be seen from the graph of the Fourier transform of $x(t)$, the graph is not symmetric with respect to y-axis, i.e., $X(j\omega)$ has no component at negative frequencies. Therefore, as it can be seen from the graph of $X_s(j\omega)$ below, the aliasing can be avoided even when $T_s = \frac{2\pi}{\Delta\omega}$ which below the Nyquist rate.

c)

The minimum sampling period, $T_s = \frac{\pi}{2\Delta\omega} \Rightarrow$ minimum sampling rate, $\frac{1}{T_s} = \frac{2\Delta\omega}{\pi}$. The Fourier transform of $X_s(j\omega)$ can be seen below. Also, the corresponding time-domain signal is band-pass as it can be seen from the graph of its Fourier transform.

Question 2

The input-output relation of the DT System is given. Thus, if we take the Fourier transform of the both sides:

$$Y(e^{j\Omega}) - \frac{1}{3}Y(e^{j\Omega})e^{-j\Omega} = \frac{2}{3}X(e^{j\Omega}) - 2X(e^{j\Omega})e^{-j\Omega}$$

$$Y(e^{j\Omega})[1 - \frac{e^{-j\Omega}}{3}] = X(e^{j\Omega})[\frac{2}{3} - 2e^{-j\Omega}] \Rightarrow H(e^{j\Omega}) = \frac{Y(e^{j\Omega})}{X(e^{j\Omega})} = \frac{2-6e^{-j\Omega}}{3-e^{-j\Omega}}$$

$$x_c(t) = \sin(1000\pi t) \text{ and } x[n] = x_c(nT) \quad \boxed{\omega_m = 1000\pi}$$

$$X_c(j\omega) = \frac{\pi}{j}(\delta(\omega - 1000\pi) - \delta(\omega + 1000\pi))$$

$$X(e^{j\Omega}) = \frac{1}{T} \sum_{k=-\infty}^{\infty} X_c\left(j\left(\frac{\Omega - 2\pi k}{T}\right)\right) = \frac{\pi}{jT}$$

$$X(e^{j\Omega}) = \sum_{k=-\infty}^{\infty} \delta\left(\frac{\Omega - 2\pi k}{T} - 1000\pi\right) - \delta\left(\frac{\Omega - 2\pi k}{T} + 1000\pi\right)$$

$\underbrace{\frac{2\pi}{T} > 2\omega_m \Rightarrow \frac{1}{T} > 1000}_{\text{to avoid aliasing}}$

If there is no aliasing, the below equation holds:

$$Y_r(j\omega) = \begin{cases} H(e^{j\omega T})X_c(j\omega), & |\omega| \leq \frac{\pi}{T} \\ 0, & \text{otherwise} \end{cases}$$

$$Y_r(j\omega) = \begin{cases} \frac{\pi}{j} \frac{2-6e^{-j\omega T}}{3-e^{-j\omega T}} [\delta(\omega - 1000\pi) - \delta(\omega + 1000\pi)], & |\omega| \leq \frac{\pi}{T} \\ 0, & \text{otherwise} \end{cases}$$

$$y_r(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} Y_r(j\omega) e^{j\omega t} d\omega$$

i)

$$\frac{1}{T} = 2\text{kHz} \Rightarrow \frac{2\pi}{T} = 2\omega_m \text{ (No aliasing)} \Rightarrow \omega_m T = \frac{\pi}{2}$$

$$y_r(t) = \frac{1}{2j} \left[\frac{2-6e^{-j\pi/2}}{3-e^{-j\pi/2}} e^{j1000\pi t} - \frac{2-6e^{j\pi/2}}{3-e^{j\pi/2}} e^{-j1000\pi t} \right] = \frac{1}{2j} [(1.2 + 1.6j)e^{j1000\pi t} - (1.2 - 1.6j)e^{-j1000\pi t}]$$

$y_r(t) = 1.2\sin(1000\pi t) + 1.6\cos(1000\pi t)$
--

ii)

Question 3

a)

If we take the Laplace transform of the both sides of the equation:

$$s^2Y(s) - sY(s) - 6Y(s) = 2sX(s) - 11X(s)$$

$$Y(s)(s^2 - s - 6) = X(s)(2s - 11)$$

$$H_1(s) = \frac{Y(s)}{X(s)} = \frac{2s-11}{(s-3)(s+2)} = \frac{-1}{s-3} + \frac{3}{s+2}$$

The pole-zero diagram of $H_1(s)$ is drawn below.

We cannot determine $h_1(t)$ unless we know the ROC.

b)

i)

If the system is stable, then ROC includes $j\omega$ -axis. Therefore, we can determine ROC as $-2 < \sigma < 3$.

$-2 < \sigma$ implies $\frac{3}{s+2}$ corresponds to right-sided time function which is $3e^{-2t}u(t)$.

$\sigma < 3$ implies $\frac{-1}{s-3}$ corresponds to left-sided time function which is $e^{3t}u(-t)$.

$$h_1(t) = e^{3t}u(-t) + 3e^{-2t}u(t)$$

ii)

If the system is causal, then ROC is the right side of the right-most pole. Therefore, we can determine ROC as $\sigma > 3$.

$\sigma > -2$ implies $\frac{3}{s+2}$ corresponds to right-sided time function which is $3e^{-2t}u(t)$.

$\sigma > 3$ implies $\frac{-1}{s-3}$ corresponds to right-sided time function which is $-e^{3t}u(t)$.

$$h_1(t) = (-e^{3t} + 3e^{-2t})u(t)$$

iii)

If the system is anti-causal, then ROC is the left side of the left-most pole. Therefore, we can determine ROC as $\sigma < -2$.

$\sigma < -2$ implies $\frac{3}{s+2}$ corresponds to right-sided time function which is $-3e^{-2t}u(-t)$.

$\sigma < 3$ implies $\frac{-1}{s-3}$ corresponds to right-sided time function which is $e^{3t}u(-t)$.
 $h_1(t) = (e^{3t} + -3e^{-2t})u(-t)$

c)

i)

The ROC is the whole s-plane.

ii)

$$H(s) = \frac{Y(s)}{X(s)} = s - 3$$

$$Y(s) = X(s)(s - 3) = sX(s) - 3X(s)$$

$$y(t) = \frac{d}{dt}x(t) - 3x(t)$$

d)

i)

Assume $h_1(t)$ is causal. Then it is not stable since the ROC does not include $j\omega$ -axis.

ii)

$$H(s) = H_1(s)H_2(s) = \frac{2s-11}{(s-3)(s+2)}(s-3)H(s) = \frac{2s-11}{s+2} = 2 - \frac{15}{s+2} \quad \text{ROC} : \sigma > -2$$

$$h(t) = 2\delta(t) - 15e^{-2t}u(t)$$

iii)

The cascaded system has a ROC which includes $j\omega$ -axis. Therefore, we can say that the cascaded system is stable although the first system is not stable. The second system is used to make the first system stable.

Question 4

a)

If $h[n]$ is real, then the following condition must be satisfied: $H(z) = H^*(z^*)$

$$H(z) = \frac{z(z-1)}{\left(z-a\left(\frac{1}{\sqrt{2}}-\frac{j}{\sqrt{2}}\right)\right)\left(z-a\left(\frac{1}{\sqrt{2}}+\frac{j}{\sqrt{2}}\right)\right)} = \left(\frac{z^*(z^*-1)}{\left(z^*-a\left(\frac{1}{\sqrt{2}}-\frac{j}{\sqrt{2}}\right)\right)\left(z^*-a\left(\frac{1}{\sqrt{2}}+\frac{j}{\sqrt{2}}\right)\right)}\right)^* = H^*(z^*)$$

Thus, $h[n]$ is a real-valued signal.

b)

c)

$$\begin{aligned} \text{If } a = \sqrt{2} &\Rightarrow H(z) = \frac{z(z-1)}{z^2-2z+2} \\ x[n] = u[n-1] &\Rightarrow X(z) = \sum_{n=-\infty}^{\infty} u[n-1]z^{-n} = \sum_{n=1}^{\infty} z^{-n} = \sum_{n=0}^{\infty} z^{-n} - 1 = \frac{1}{z-1}, |z| < 1 \\ Y(z) = X(z)H(z) &= \frac{z^{-1}}{z^2-2z+2} = \frac{z^{-1}}{(z-1+j)(z-1-j)}, \text{ ROC: } |z| > \sqrt{2} \\ Y(z) &= \frac{z^{-1}}{(1-(1-j)z^{-1})(1-(1+j)z^{-1})} = \frac{c_1}{1-(1-j)z^{-1}} + \frac{c_2}{1-(1+j)z^{-1}} \\ Y(z) &= \frac{j/2}{1-(1-j)z^{-1}} + \frac{-j/2}{1-(1+j)z^{-1}} \Rightarrow y[n] = \frac{j}{2}(1-j)^n u[n] - \frac{j}{2}(1+j)^n u[n] \end{aligned}$$

d)
